# Discussion 2: Sml<sub>2</sub> mediated coupling

1. Sml<sub>2</sub> mediated coupling reaction developed by Skrydstrup group ref 1

1-1: Back ground of acyl radical

The addition of acyl radicals to olefins is known as one of the C-C bond formation reactions. However, acyl radicals have a potential for decarbonylation in addition to radical addition reactions. The reaction rate of the decarbonylation process depends on the structure of the acyl radical.

As illustrated in the box below, when the acyl radical undergoes decarbonylation and generated radical is primary radical, the reaction rate constant for the decarbonylation reaction is small due to the instability of the generated radical. Conversely, if the resulting radical is tertiary radical, the rate constant for this reaction becomes considerably larger.

## 1-2: Reaction design

R 
$$X$$
  $X = \text{ester}$  amide nitrile  $X$   $X = \text{ester}$   $X = \text{este$ 

- •It has been reported that imides can be readily reduced using Sm<sup>II</sup>I<sub>2</sub>. ref. 4
- •Regioselective reduction of the *N*-acyl carbonyl group was anticipated due to its lower  $\pi^*_{C=O}$  orbital in comparison to the same  $\pi^*_{C=O}$  orbital of oxazolidine.
- -> Coupling products retained the corbonyl group.

# 2: Possible reaction mechanism

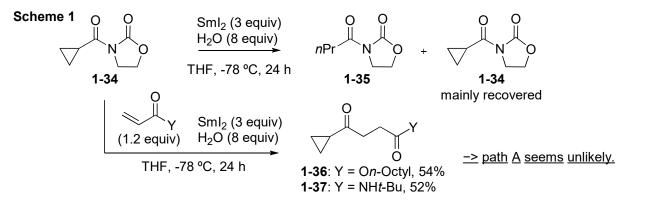

path A: Reduction of amide precedes 
$$\alpha,\beta$$
-unsaturated ester 
$$\begin{array}{c} Sm^{||}|_2 \\ \hline Sm^{||}|_2 \\ \hline$$

path B: Reduction of  $\alpha,\beta$ -unsaturated ester precedes amide

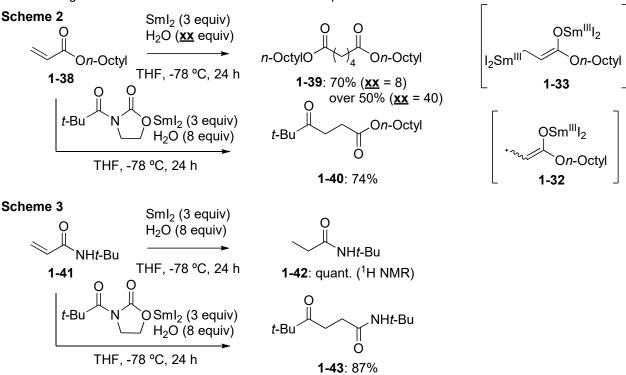

1-23 
$$\xrightarrow{Sm^{\parallel}l_2}$$
  $\xrightarrow{Sm^{\parallel}l_2}$   $\xrightarrow{Sm^{\parallel}l_2}$   $\xrightarrow{Sm^{\parallel}l_2}$   $\xrightarrow{On\text{-Octyl}}$   $\xrightarrow{Sm^{\parallel}l_2}$   $\xrightarrow{On\text{-Octyl}}$   $\xrightarrow{I-32}$  1-26

3: Mechanistic studies

3-1: Coupling reaction toward cyclopropyl derivative 1-32

3-2: Investigation of whether it is a radical reaction or a polar reaction.

Organosamarium species (Sm<sup>III</sup>) are classified as hard Lewis acids, and 1,2-addition is favored over 1,4-addition. Therefore, dimer **1-39** was generated by radical addition to **1-38** of formed organosamarium species, rather than conjugate addition. Moreover, the fact that increasing the amount of water did not significantly decrease the yield supports the mechanism of radical addition.

**CbzHN** 

1-46

not obtain

Sml<sub>2</sub> (3 equiv)  

$$H_2O$$
 (8 equiv) CbzHN  
THF, -78 °C, 24 h

58%

In the coupling reaction using pentafluorophenyl ester (1-43) which has better leaving group compared to oxazolidinone, 1-45 was obtained and starting material was recovered. not

Judging from the results, path B is more favorable.

### 4: Reaction rate constant

substrate	rate constant (s <sup>-1</sup> )	
1-47	< 1.90 x 10 <sup>-3</sup>	
1-40	3.80 x 10 <sup>-3</sup>	
1-37	8.10 x 10 <sup>-3</sup>	

The reduction rate of  $\alpha,\beta$ -unsaturated carbonyl compounds is faster than oxazolidinone.

# 5: Chelation effect (reduction rate constant)

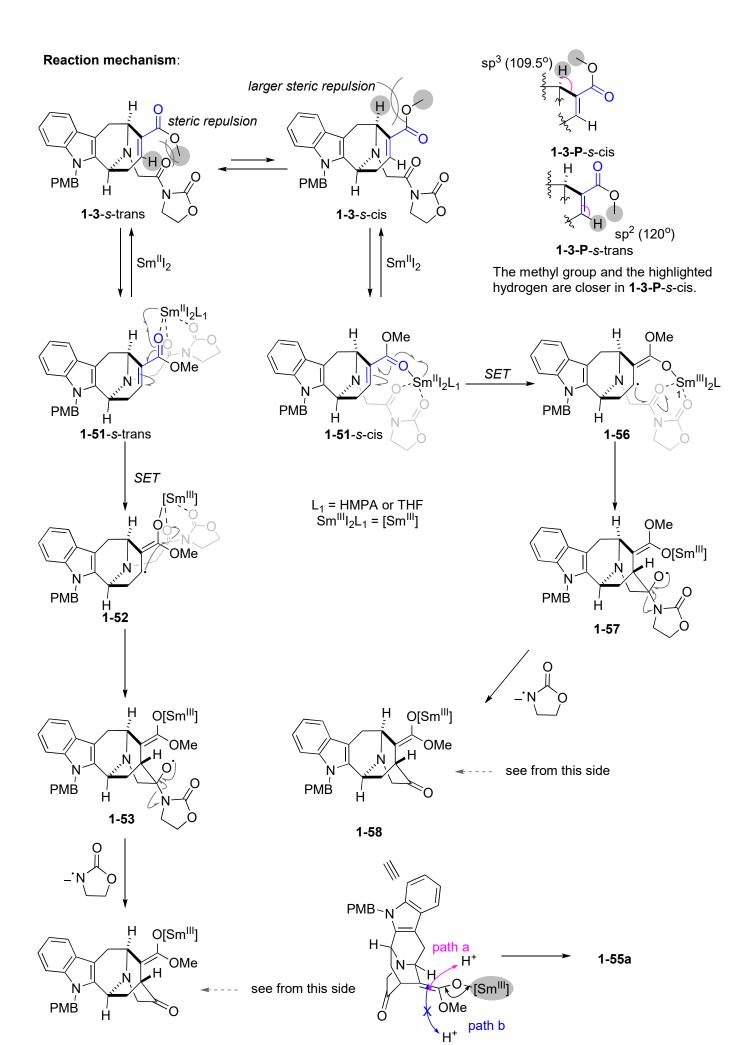

substrate	rate constant (M <sup>-1</sup> s <sup>-1</sup> )
1-48	7 x 10 <sup>-4</sup>
1-49	2.2 x 10 <sup>-1</sup>
1-50	7.5 x 10 <sup>2</sup>

A comparison of the reduction using Sml<sub>2</sub> with 1-48, 1-49, and 1-50 was conducted to investigate the effect of coordination and chelation on reaction rate. The fact that 1-49 and 1-50 have higher rate constant suggests that chelation enhances the reaction rate in reduction using Sml<sub>2</sub>.

## 6: Redox potential of Sm<sup>II</sup>I<sub>2</sub>

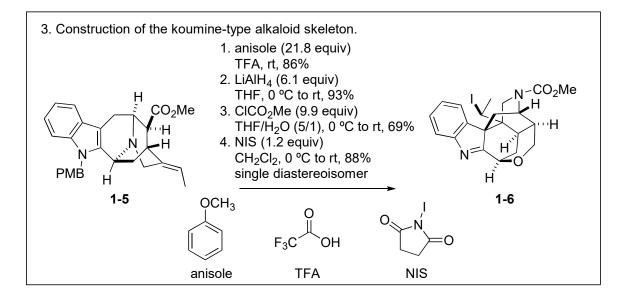

entry	reductant	solvent	E <sub>1/2</sub> [V] (vs. SCE)
1	$\mathrm{Sm^{II}I_{2}}$	THF	-0.98
2	$\mathrm{Sm^{II}I_{2}(H_{2}O)_{n}}$	THF	-1.3
3	Sm <sub>II</sub> I <sub>2</sub> (HMPA) <sub>4</sub>	THF	-1.75

The change in the chemical species coordinating to Sml<sub>2</sub> alters the redox potential, that is, the reduction potential of Sml<sub>2</sub>.

1-58' -7-1-54

The highlighted Sm<sup>III</sup> becomes a significantly large chemical species, including ligands. Therefore, these ligands are directed towards the sterically available space below the molecule. Protonation is observed to occur in a manner that avoids the large Sm<sup>III</sup> species.

### Reaction mechanism:

**Discussion 3:** role of anisole <sup>ref. 5</sup> proposed side reaction

capturing the benzyl cation

Benzyl cation generated from the deprotection of p-methoxybenzyl (PMB) is expected to undergo a side reaction. For example, tertiary amine of **1-5** or **1-65** can attack the cation and be p-methoxybenzylation. Addition of 21.8 equivalents of anisole can suppress this side reaction by trapping the generated benzyl cation.

### Discussion 4: stereoselectivity
